Columns that have only one unique value (low variance) across all rows are not useful for analysis as they do not contribute any information that can differentiate between rows. For example, pcircle has only 1 unique value, so it likely won't be useful in any analysis.

In [6]:
```
import matplotlib.pyplot as plt

# thresholds based on percentiles
low_balance_threshold = df['rental30'].quantile(0.25)
high_balance_threshold = df['rental30'].quantile(0.75)

# categorize balance based on thresholds
def categorize_balance(value):
    if value <= 0:
        return 'no balance'
    elif value <= low_balance_threshold:
        return 'low balance'
    elif value <= high_balance_threshold:
        return 'average balance'
    else:
```

```
        return 'high balance'

df['balance_group'] = df['rental30'].apply(categorize_balance)

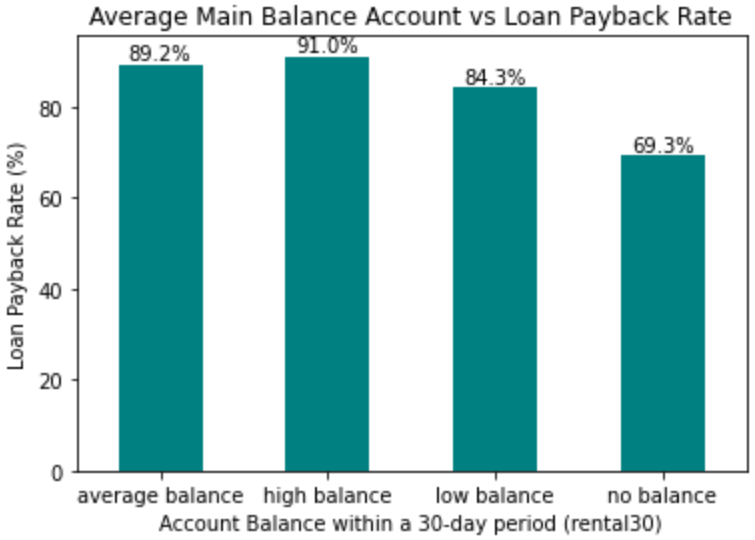
#calculate the percentage of labels for each balance group
percentage = pd.crosstab(df['label'], df['balance_group'], normalize='columns').apply(lambda x: x * 100)
percentage = percentage.transpose()

plot_balance = percentage[1].plot(kind='bar', color='teal', figsize=(6, 4))

plt.title('Average Main Balance Account vs Loan Payback Rate')
plt.ylabel('Loan Payback Rate (%)')
plt.xlabel('Account Balance within a 30-day period (rental30)')
plt.xticks(rotation='horizontal')

for rec, label in zip(plot_balance.patches, percentage[1].round(1).astype(str)):
    plot_balance.text(rec.get_x() + rec.get_width() / 2,
                      rec.get_height() + 1,
                      label + '%',
                      ha='center',
                      color='black')

plt.show()
```



High balance leads to higher payback rate. Accounts with an average balance have an 89.2% payback rate, while those with a low balance have a significantly lower payback rate at 84.3%. This indicates that as the account balance decreases, so does the likelihood of loan repayment. No balance has the lowest payback rate. The graph illustrates a clear trend that the higher the account balance, the higher the loan payback rate

```

Based on the aforementioned outcomes, it is evident that the K Nearest Neighbor model outperforms the others. Through a comprehensive comparison of bias error and variance error across all algorithms, it is concluded that KNN is the most effective, and therefore, it will be employed for predicting loan defaulters.
